Prenatal Joubert Syndrome and Related Disorders (JSRD) Panel Sequence Analysis and Exon-Level Deletion/Duplication Testing of 29 Genes

**Panel Gene List:** AHI1, ARL13B, B9D1, B9D2, C5orf42, CC2D2A, CEP41, CEP104, CEP120, CEP290, CSPP1, IFT172, INPP5E, KIAA0586, KIF7*, MKS1, NPHP1, NPHP3, OFD1, RPRGIP1L, TCTN1, TCTN2, TCTN3, TMEM67, TMEM138, TMEM216, TMEM231, TMEM237, TTC21B. *Only whole gene deletions/duplications may be detected for the KIF7 gene

**Clinical Features:**
Joubert syndrome is a brain malformation disorder characterized by the presence of a midbrain-hindbrain abnormality called the molar tooth sign, which results from cerebellar hypoplasia, thickened superior cerebellar peduncles, and a deepened interpeduncular fossa.1-3 Affected individuals demonstrate hypotonia, developmental delay, and variable cognitive impairment. Breathing abnormalities and oculomotor apraxia may also be observed. Retinal dystrophy, renal disease, occipital encephalocele, polydactyly, hepatic fibrosis, and other abnormalities are seen in variant forms of this disorder. Renal disease can range from nephronophthisis to cystic renal dysplasia.4 Joubert syndrome shares phenotypic overlap with other ciliopathies, including Bardet-Biedl, COACH, and Meckel-Gruber syndromes, and all of these disorders show significant clinical variability.1,5-8 Meckel-Gruber syndrome, in particular, shows close overlap with Joubert syndrome and is characterized by occipital encephalocele, cystic kidneys, hepatic defects, and other anomalies.9 A diagnostic algorithm has been proposed to address the clinical and genetic heterogeneity and aid in the molecular diagnosis of Joubert syndrome.1,2

Joubert syndrome and related disorders (JSRD) are identified in the prenatal period by the presence of the molar tooth sign on ultrasound.1 Additional features including other structural brain malformations, encephalocele, renal disease, polydactyly, and cleft lip/palate may also be seen.1 Other imaging methods such as 3D ultrasound or fetal MRI can be used to evaluate and diagnose JSRD in utero.1 Due to genetic heterogeneity and overlapping phenotypes, the specific diagnosis cannot be determined accurately with imaging alone. When available, genetic testing can aid in determining the precise diagnosis after the differential has been established by imaging.

**Inheritance Pattern/Genetics:**
The prevalence of Joubert syndrome and its variant forms is estimated to be approximately 1:100,000.1 Many genes have been associated with Joubert syndrome, although some are very rarely involved.10 These genes have important functions in the development of cilia in various organs.3 Cilia play a role in intraflagellar transport, cell division, tissue differentiation,
Test Methods:

Using genomic DNA extracted from the submitted specimen, the complete coding regions and splice site junctions of the genes tested are enriched using a proprietary targeted capture system developed by GeneDx for next-generation sequencing with CNV calling (NGS-CNV). The enriched targets are simultaneously sequenced with paired-end reads on an Illumina platform. Bi-directional sequence reads are assembled and aligned to reference sequences based on NCBI RefSeq transcripts and human genome build GRCh37/UCSC hg19. After gene specific filtering, data are analyzed to identify sequence variants and most deletions and duplications involving coding exons; however, technical limitations and inherent sequence properties effectively reduce this resolution for some genes. Alternative sequencing or copy number detection methods are used to analyze or confirm regions with inadequate sequence or copy number data by NGS. Reportable variants include pathogenic variants, likely pathogenic variants and variants of uncertain significance. Likely benign and benign variants, if present, are not routinely reported but are available upon request.

The technical sensitivity of sequencing is estimated to be >99% at detecting single nucleotide events. It will not reliably detect deletions greater than 20 base pairs, insertions or rearrangements greater than 10 base pairs, or low-level mosaicism. The copy number assessment methods used with this test cannot reliably detect copy number variants of less than 500 base pairs or mosaicism and cannot identify balanced chromosome aberrations. Assessment of exon-level copy number events is dependent on the inherent sequence properties of the targeted regions, including shared homology and exon size. Gene specific exclusions for exon-level deletion/duplication testing for this panel are: KIF7 gene, only whole gene deletions or duplications may be detected.
Additionally, genotype analysis of maternal and fetal DNA for several polymorphic markers to test for maternal cell contamination will be performed. Therefore, in all prenatal cases, a maternal sample should accompany the fetal sample.

**Test Sensitivity:**
The clinical sensitivity of sequencing and deletion/duplication analysis of the genes included in this panel in prenatal cases ascertained based on fetal ultrasound abnormalities is currently unknown, and the clinical sensitivity of this panel depends in part on the clinical phenotype of the fetus. Specific information about the diagnostic yield for each gene in selected populations is summarized in the following table(s).
